# THE GAVINO WORD ASSOCIATION NORMS* 

Jasmin A. Gavino<br>University of the Philippines

#### Abstract

Norms for word associations to one hundred stimulus words from 1,000 University of the Philippines students are listed in this article. Essentially the Philippine norms were significantly different from the Russel and Jenkins and the Palermo and Jenkins list but was not significantly different from the Kent and Rosanoff list.

As early as 1910 Kent and Rosanoff published norms for word associations. From then on at least three others have been widely known: Russel and Jenkins (1954), Palermo and Jenkins (1964), and Riegel (1965). Without these norms a variety of researches would have been extremely difficult, if not completely impossible. Previous use include the construction of association inventories for deviant ideation, ${ }^{1}$ the analysis of the psychological structure of meaning, ${ }^{2}$ the discovery of developmental trends in children's associations ${ }^{3}$ and its implications for verbal learning as well as verbal behavior.

In an earlier paper ${ }^{4}$ on responses of Filipino students to personality test items with a forcedchoice word association format, students revealed a significant tendency to change their responses on the two forms of the tests that are

[^0]supposed to be equivalent. While a variety of possible explanations were raised then, one of the simplest is that the associations to translations of the stimuli are not the same, even if they were given by the same bilingual subject. The necessity for establishing Filipino norms to the Kent and Rosanoff stimuli and their translations in Pilipino was recognized. Hence, the Gavino Association Norms.

The present compilation of free association responses utilized the original one hundred stimulus words from the Kent and Rosanoff word list. Theoretically any set of words could have been used for the purpose, but the Kent and Rosanoff list was used because it has been the basis for personality tests such as the Maller's Controlled Association Test and Bruce's Association Adjustment Inventory. It is hoped that in the future similar adjustment inventories would be constructed for use in the Philippines.

Associations of homosexuals, maladjusted students with disciplinary problems, and children in high school (1st and 2nd years) and the grade school (grade 5 and 6 ) are being compiled to constitute a homosexual scale, a simple maladjustment scale, and a juvenile scale, respectively. The purpose of this paper, therefore, is primarily to provide association norms in a form that is comparable to existing word lists and to raise the question of linguistic equivalence on an associational task.

## Method

## Subjects

One thousand freshmen and sophomore students at the - University of the Philippines ${ }^{\text {w }}$ were given the hundred stimulus words in partial fulfillment of the laboratory requirement in Elementary Psychology. The task was given in groups of forty to fifty subjects at a time with 3 to 4 proctors in attendance.

## Procedure

The directions were read and the proctors checked if they were followed correctly. The directions are: "Write the first word that comes to your mind when you read the word on the left hand column. Do not skip any of the words and answer them in the order that they are presented to you. You do not have to hurry, but if you take too long you are not following the directions." There was of course no time limit and usually students completed the task within 20-30 minutes.

## Results and Discussion

The tally of responses to the 100 words yielded a volumnious amount of data only part of which is analyzed here. Appendix A shows the most frequently associated words to the different stimuli. These are ranked according to frequency of occurrence. Generally the highest ten words have been listed, but there were instances when the tenth rank was shared by several words so that more than ten response words appear in the list.

The first comparison is on thirty randomly chosen words and their associates. Appendix B presents the three most frequent responses on these 30 stimuli. Table 1 compares the primary

| C |  |  | .41 |

responses to the four word lists. Eighteen of the 30 stimuli have the same primary response. For 6 of the 30 stimuli, the primary response to the Gavino list is similar to that of at least one other word list. Therefore, on 23 out of 30 items the primary responses were similar. This is a large ratio ( $77 \%$ ) and it would seem that the distributions are comparable. However, when the means were compared for significant differences, the Gavino list was significantly different from two (Russell and Jenkins and Palermo and Jenkins) of the three word lists. The difference between the mean percentages could be accounted for by the higher dominance of the S-R parts in the American norms. Table 2 summarizes the results. It was also noted that the three American lists were not significantly different from each other.

The next comparison was on 39 primary responses to the stimuli in English and their equivalent in Pilipino. Table 3 presents the pairs of words that are most frequently associated. Twenty-four out of 39 ( $61.5 \%$ ) primary responses in English was not the same as the primary response to the Pilipino translation. This indicates that Pilipino-English bilinguals have different associations to words depending on the language in which the stimuli is presented.

On the 15 items where the primary tesponse to English and Pilipino were equivalent the mean percentages of the primary responses were compared but this was not found to be significantly different.Since the sample for the Pilipino stimuli was less than a thousand ( $\mathrm{n}=500$ ), to make the frequencies comparable they were multiplied by two. It was assumed that if the sample were doubled the probability of subjects responding in a similar fashion is very high. This seemed to be a valid assumption, since a clustering of responses in the Pilipino task was more marked than in English. It also seemed that the S-R pairs were more strongly associated if the frequency index was taken as a measure of the strength of association. (Refer to Appendix C for the three most frequently associated words to the Pilipino stimuli.) The compilation of norms for Pilipino stimuli is warranted and necessary, and the adoption of the English norms will not suffice.

Local use of word association inventories, such as the Controlled Association Test and the Association Adjustment Inventory is open to question, since they are based on word association norms that are not comparable to Philippine norms. The construction of a new association inventory with empirically valid scales for Fili-
pino groups is under preparation. This should be more meaningful for selection and clinical purposes.

Other studies can be conducted using the Association Norms. For example, the differences
in the structure of psychological meaning between concepts in English and in Pilipino can be explored or the systematic developmental changes in association can provide information regarding the acquisition of concepts.
