# TESTING THE INDEPENDENCE OF REGRESSION ERRORS* 

FE R. BERNARDO**

## I. The Linear Regression Model

Consider the equation

$$
\mathrm{L}=\mathrm{HA}
$$

where $L=\left(1_{1}, 1_{2}, \ldots, 1_{n}\right)$ ' is a ( $n, 1$ ) matrix of unknown real numbers, $A=\left(a_{1}, a_{2}, \ldots, a_{k}\right)$ is a ( $K, 1$ ) matrix of unknown real numbers and $H=$ (hij) $(i=1, \ldots, n$; $j=1,2, \ldots, k$ ) is a ( $n, k$ ) matrix of known real numbers.

The quantities $1_{1}(i=1,2, \ldots, n)$ are not directly observed. However they are supposed to differ from the observed quantities $Z_{1}(i=1,2, \ldots, n)$ by unknown random variables $w_{1}$ so that for every $i$,

$$
Z_{1}=1_{i}+w_{1}
$$

If $W=\left(W_{1}, W_{2}, \ldots, w_{n}\right)^{4}$ and $\left.Z=z_{1}, z_{2}, \ldots z_{n}\right)^{\prime}$ then (1.1) maybe written in matrix form as

$$
\begin{gather*}
\mathrm{Z}=\mathrm{L}+\mathrm{W} \\
\text { or } \mathrm{Z}=\mathrm{HA}+\mathrm{W} \tag{1.2}
\end{gather*}
$$

The random variable $W$ is assumed to be multivariate normal with zero mean and variance-covariance matrix

$$
V(W)=\left\{\begin{array}{cccc}
s_{1}{ }^{2} & 0 & \ldots & 0 \\
0 & s_{2}{ }^{2} & \ldots & 0 \\
0 & \cdot & \ldots & \dot{a} \\
0 & 0 & \ldots & s_{n}{ }^{2}
\end{array}\right\}
$$

where $s_{1}{ }^{2}$ is the variance of $w_{i}$. It is also assumed that each of the $s_{1}{ }^{2}$ is a multiple of an unknown quantity $s^{2}$,
that is

$$
\mathrm{s}_{\mathrm{i}}=\frac{\mathbf{s}_{2}}{\mathrm{~d}_{\mathrm{i}}}
$$

where the $d_{i}$ 's are known "weights"
Let $\mathrm{D}=\left(\sqrt{ } \mathrm{d}_{\mathrm{i}} \delta_{\mathrm{ij}}\right)$, where $\delta_{1 \mathrm{j}}$ is the Kronecher symbol. Applying the transformation

$$
\underset{\sim}{Y}=\mathrm{DZ}
$$

equation (1.2) becomes

$$
\begin{equation*}
\mathbf{Y}=\mathbf{X A}+\overline{0} \tag{1.3}
\end{equation*}
$$

where $\mathrm{X}=\mathrm{DH}, \mathrm{U}=\mathrm{DW}$. Therefore the first two moments of $U$ are

$$
\begin{aligned}
& \mathrm{E}(\bar{U})=\mathrm{DE}(\mathrm{~W})=0 \\
& \mathrm{~V}(\overline{\mathrm{U}})=\mathrm{D}^{2} \mathrm{~V}(\mathrm{~W})=\left(\mathrm{d}_{\mathrm{i}} \mathrm{~s}_{\mathrm{i}}{ }^{2} \delta_{\mathrm{ij}}\right)=\mathrm{s}^{2} \mathrm{I} .
\end{aligned}
$$

Since $\bar{U}=D W$ is a linear transformation, then $\bar{U}$ is a multinormal vector (with mean zero and variance-covariance matrix $\mathrm{s}^{2} \mathrm{I}$ ).

Equation (1.3). is known as the linear regression model.
Since (1.3) has more unknowns than equations, it has no unique solution. However, A can be estimated so that $U \prime U$ is minimum. This estimator of $A$, called the least squares estimator, is

$$
\hat{\mathbf{A}}=\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime} \mathrm{Y}
$$

Under the assumptions on X and U mentioned above, we have

$$
\begin{aligned}
\mathrm{E}(\hat{\mathbf{A}}) & =\mathrm{E}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime}(\mathrm{XA}+\mathrm{U}) \\
& =\mathrm{A}+\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime} \mathrm{E}(\overline{\mathrm{U}}) \\
& =\mathrm{A}
\end{aligned}
$$

and

$$
\begin{aligned}
V(\hat{A}) & =\left(X^{\prime} X\right)^{-1} V(Y)\left(X^{\prime} X\right)^{-1} X^{\prime} \\
& =\left(X^{\prime} X\right)^{-1} X^{\prime}\left(\mathrm{s}^{2}\right) X\left(X^{\prime} X\right)^{-1} \\
& =S^{2}\left(X^{\prime} X\right)^{-1}
\end{aligned}
$$

The likelihood function of $\bar{U}$ is

$$
\mathrm{L}=\frac{1}{(2 \pi)^{n / 2} \mathrm{~S}^{\mathrm{n}}} \exp \left[-\frac{\mathrm{U} \mathrm{U}}{2 \mathrm{~s}^{2}}\right]
$$

Hence:

$$
\operatorname{In} L=-\frac{\mathrm{n}}{2} \ln 2 \pi-\frac{\mathrm{n}}{2} \ln \mathrm{~s}^{2} \frac{1}{2 \mathrm{~s}^{2}}(\mathrm{Y}-\mathrm{XA})^{\prime}(\mathrm{Y}-\mathrm{XA})
$$

and $\ln \hat{L}=-\frac{n}{2} \ln 2 \pi-\frac{n}{2} 1 \operatorname{si}^{2} \frac{-1}{2 s^{2}}(Y-X \hat{A}),(Y-X \hat{A})$,
so that $\quad \frac{a^{2} \ln L}{\partial \hat{A}^{2}}=\frac{-X^{\prime} X}{s^{2}}$.
Thus, Fisher's information matrix 1 is

$$
\begin{aligned}
I & =-E\left[\frac{a^{2} \ln L}{\partial \hat{A}^{2}}\right] \cdot \\
& =-E\left[-\frac{X^{\prime} X}{s^{2}}\right]=\frac{X^{\prime} X}{s^{2}}=[V(\hat{A})] \cdot[]^{[10}
\end{aligned}
$$

We therefore conclude $\hat{\mathbf{A}}$ is an unbiased estimator of $\mathbf{A}$, and that in the class of all unbiased estimators of $\mathrm{A}, \hat{\mathrm{A}}$ has the least variance.

However, when the components of $\bar{U}$ are not independent of each other, then $\hat{\mathbf{A}}$ is no longer the best estimator of A. This is proven in section 3.1 of text.

It is therefore necessary to test for the independence of the $\bar{U}_{1}$ 's whenever least sauares regression methods are used, that is test the hypothesis

$$
\begin{equation*}
\mathrm{H}_{\mathrm{o}}: \overline{\mathrm{U}} \quad \Gamma \mathrm{~N}\left(0, \mathrm{~s}^{2} \mathrm{I}\right) \tag{1.4}
\end{equation*}
$$

against the hypothesis

$$
\begin{equation*}
\mathrm{H}_{\mathrm{u}}: \overline{\mathrm{U}} \quad / \mathrm{N}\left(0, \mathrm{~s}^{2} \Sigma\right) \tag{1.5}
\end{equation*}
$$

when $\Sigma$ is a given matrix different from $I$.
Since the errors $U_{i}$ 's are unknown the test must be based on the residuals from the estimated regression line 0 . (also called the least squares estimator of U ) which is defined as

$$
\begin{aligned}
\hat{0} & =\mathrm{Y}-\mathrm{X} \hat{\mathrm{~A}} \\
& =\left[\mathrm{I} \overrightarrow{\mathrm{X}}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime}\right] \mathrm{Y} \\
& =\mathrm{M} \mathrm{M} \mathrm{U}
\end{aligned}
$$

Now,

$$
\begin{aligned}
\mathrm{V}(\hat{\mathrm{U}}) & =\mathrm{M} \mathrm{~V}(\overline{\mathrm{U}}) \mathrm{M}^{\prime} \\
& =\mathrm{M}\left(\mathrm{~s}^{2} \mathrm{I}\right) \mathrm{M}^{\prime} \\
& =\mathrm{s}^{2} \mathrm{M}
\end{aligned}
$$

under the null hypothesis (1.4). This implies that the residuals are correlated. Consequently, the ordinary tests of independence can not be used to test (1.4) against (1.5).

## II. Tests of the Null Hypothesis

Von Neuman, reviving a procedure introduced in the 19th century by a German scientist, tackles the problem of testing for independence of regression errors by using the ratio of the mean square successive difference to the variance, that is:

$$
\begin{align*}
& Q=\frac{\frac{1}{\mathrm{n}-1} \underset{\mathrm{i}=2}{\mathrm{n}}\left(\hat{u}_{\mathrm{i}}-\hat{\mathrm{u}}_{1-1}\right)^{2}}{1 \mathrm{n}} .  \tag{2.1}\\
& \overline{\mathrm{n}} \underset{\mathrm{i}=1}{\sum}\left(\hat{\mathrm{u}}_{\mathrm{i}}-\overline{\hat{\mathrm{u}}}\right)^{2}
\end{align*}
$$

The null hypothesis (1.4) is rejected at significance level $\mathcal{L}$ whenever an observed $Q<Q_{2}$ where $\operatorname{Pr}\left(Q<Q_{\dot{2}} / H_{0}\right)=\mathscr{L}$.
T.W. Anderson and R. L. Anderson studied the model

$$
\begin{equation*}
y_{i}-\mu_{i}=\left(y_{i-1}-\mu_{i-1}\right)+\epsilon_{i} \quad(i=1, \ldots, n) \tag{2.2}
\end{equation*}
$$

where the $y_{1}$ 's are observed values, the $\epsilon_{i}$ 's are random errors. which are normally and independently distributed with mean zero and variance $\delta^{2}$; while the $\mu_{1}$ 's are linear combinations. of Fourier terms. They then defined the circular serial correlation coefficient of this model as

where $m_{0}=m_{n}$ and $m_{i}$ is an estimate of $u_{1}$. This statistic can be used to test the null hypothesis

$$
\mathrm{H}_{\mathrm{o}}: P=0
$$

against the alternative hypothesis

$$
\begin{aligned}
& \mathrm{H}_{\mathrm{n}}: \rho>0 \\
& \mathrm{H}_{\mathrm{a}}:
\end{aligned}: \rho<0
$$

where the respective critical regions are
with $R_{1}$ and $R_{2}$ being the critical values corresponding to a given significance level.

Suppose that the alternative to the null hypothesis (1.4): is that the $u_{1}$ 's follow a stationary Markoff scheme, i.e.

$$
\begin{equation*}
u_{i}=P\left(u_{i-1}\right)+\epsilon_{i}(i=\ldots-1,0,1, \ldots) \tag{2.4}
\end{equation*}
$$

where $|\beta| \leq 1$ and $\epsilon_{1} \quad \mathrm{~N}\left(0, \mathrm{~s}^{2}\right)$. Then the hypotheses (1.4)
and (1.5) are equivalent to the hypotheses

$$
\begin{align*}
& \mathrm{H}_{0}{ }^{*}: \rho=0  \tag{2.5}\\
& \mathrm{H}_{*}^{*}: P>0 \tag{2.6}
\end{align*}
$$

respectively.
Now, the regression equation (1.3) can be written as

$$
y_{1}=\sum_{j=1}^{k} a_{1} x_{11}+u_{i} \quad(i=1, \ldots, n) .
$$

Then (2.4) becomes

$$
y_{1}-\sum_{j=1}^{k} a_{j} X_{i=j}=P\left(y_{i=1}-\sum_{j=1}^{k} a_{j} X_{i-1 j}\right)+\epsilon_{i}(j=1, \ldots, n)
$$

which falls under the model (2.2) with $\mu_{1}=\sum_{i=1}^{n} a_{i} X_{i j}$.
Therefore, when the regression vectors, that is the culomns of the matrix $X$ in the regression model (1.3) coincide with vectors $\left(\cos 2 \Pi i, \cos 4 \Pi i, \ldots, \cos \frac{2_{\mathrm{n}} \pi_{1}}{n}\right)$, and

$$
\mathrm{n} \quad \mathrm{n}
$$

$$
R=\frac{\left.\sum_{i=1}^{n} y_{i}-m_{i}\right)\left(y_{j-1}-m_{i-1}\right)}{\sum_{\substack{i=1 \\ n}}\left(y_{1}-m_{i}\right)^{2}}=\frac{\sum_{i=1}^{n} \hat{u}_{1} \hat{u}_{1-1}}{\sum_{\substack{=1 \\ n}}^{\hat{u}_{i}^{2}}}
$$

can be used to test hypothesis (2.5) against hypothesis (2.6) with critical regions defined in (2.3).

The most commonly used test procedure is the one introduced by Durbin and Watson. The statistic used us

$$
\begin{gathered}
d=\frac{\hat{\hat{0}} A_{d} \hat{\hat{\sigma}}}{\hat{\sigma^{\prime}}, \hat{U}} \\
A_{d}=\left\{\begin{array}{cccccc}
1 & -1 & 0 & \cdots & 0 & 0 \\
-1 & 2 & -1 & \cdots & 0 & 0 \\
\dot{0} & 0 & 0 & \cdots & -1 & 1
\end{array}\right\}
\end{gathered}
$$

The exact distribution of d was found by Durbin-Watson using the Imhof method. But because of the fact that $\dot{U}=\left[\mathrm{I}-\mathrm{X}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{XI}\right] \mathrm{U}$, the distribution of d depends on X . Hence its significance points can be tabulated only for a given $X$, implying that these significance points will have to be computed everytime this test procedure is used.

Durbin and Watson showed that when S of the K regression vectors coincide with $S$ of the latent vectors of $A_{d}$, then bounds of $d$ can be found equal to

$$
\begin{aligned}
& r_{1}=\frac{\sum_{i=1}^{n-k} \lambda_{1} z_{i}{ }^{2}}{\sum_{i=1}^{n-k} z_{i}^{2}} \\
& r_{u}=\frac{\sum_{i=1}^{n-k} \lambda_{1}+{ }_{k-s} z_{1}}{\sum_{i=1}^{n-k} z_{1}{ }^{2}}
\end{aligned}
$$

where $\lambda_{1}, \ldots, \lambda_{n-s}$ are the eigen values associated with the remaining $n$-s eigenvectors of $\mathrm{A}_{d}$. Now, when a constant is fitted in the regression model, the first column of the $\mathbf{X}$ matrix consists of all ones. Hence it coincides with the eigen-
vector of $\mathrm{A}_{d}$ corresponding to the zero eigenvalue. Thus there exists bounds of $d$, that is,

$$
d_{l}<d<d u
$$

where

$$
\begin{aligned}
& d \mathrm{~L}=\frac{\sum_{\mathrm{i}=1}^{\mathrm{n}-\mathrm{k}} \lambda_{i} \mathrm{z}_{\mathrm{i}}{ }^{\mathrm{n}-\mathrm{k}} \mathrm{z}_{\mathrm{i}}{ }^{2}}{\mathrm{i}=1} \\
& \text { n-k } \\
& d u=\frac{\sum_{i=1}^{\sum} \lambda_{i}+{ }_{k-1} z_{i}{ }_{i}}{\sum_{\mathrm{j}=1}^{\mathrm{n}=1} \mathrm{z}_{\mathrm{i}}{ }^{2}}
\end{aligned}
$$

Instead of looking for the significance points of d, the following procedure called the "bounds test" maybe used:
reject $\mathrm{H}_{\mathrm{o}}$ whenever computed $\mathrm{d}<\mathrm{d} \mathrm{L}$
do not reject $H_{0}$ whenever computed $d>d u$
test inconclusive if computed $d$ is between $d \stackrel{a}{ }$ and $d u$.
This dependence on X of the distribution of test statistics based on the least squares estimator 0 of $U$ led to the discovery of other estimators of $U$.

Theil is the first to introduce an estimator of U which is independent of X, the BLUS estimator $\mathrm{U}^{*}$. He constructed $\mathrm{U}^{*}$ with variance-covariance matrix $\mathrm{s}^{2} \mathrm{I}$ and such that it is also best linear unbiased estimator of U . Because of this additional restriction on $\mathrm{U}^{*}$, it can estimate only $\mathrm{n}-\mathrm{k}$ of the errors $u_{1}, u_{2}, \ldots, u_{n}$. He therefore partitioned the matrices in the regression equation (1.3) into

$$
\left\{\frac{\mathrm{Y}_{0}}{\mathrm{Y}_{1}}\right\}=\left\{\frac{\mathrm{X}_{0}}{\mathrm{X}_{1}}\right\} A+\left\{\frac{\mathrm{U}_{0}}{\mathrm{U}_{1}}\right\}
$$

where $U_{0}$ consists of the $K$ components of $U$ which are not represented in $\mathrm{U}^{*}$. The matrix M is also partitioned into

$$
\mathbf{M}=\left\{\frac{M_{00} \mid M_{01}}{M_{1} 0 \mid M_{11}}\right\}
$$

where $M_{0}$ is ( $k, k$ ) and $M_{11}$ is a principal ( $n-k, n-k$ ) minor. Theil then derived $U^{*}$ in terms of $U$ as

$$
\mathrm{U}^{*}=\hat{\mathrm{O}}_{1}+\sum_{\mathrm{i}=1}^{\mathrm{k}}\left(\frac{1}{\sqrt{ } \mathrm{~g}_{1}} \text { 1) } \mathrm{P}_{\mathrm{i}} \mathrm{P}_{\mathrm{i}}^{\prime} \hat{\mathrm{O}}_{\mathrm{i}}\right.
$$

where $\mathcal{O}=\left\{\frac{\tilde{\sigma}_{0}}{\sigma_{1}}\right\}$, and $g_{i}(i=1, \ldots, k)$ are the $K$ roots of $M_{11}$
which are less than one, and $P_{1}$ are its corresponding eigenvectors. The von Neuman ratio of $U^{*}$

$$
\begin{equation*}
\mathrm{Q}^{*}=\frac{\sum_{\mathrm{i}=2}^{\mathrm{n}-\mathrm{k}}\left(\mathrm{u}_{\mathrm{i}}^{*}-\mathrm{u}_{1-1}^{*}\right)^{2}}{\sum_{\mathrm{i}=1}^{\mathrm{n}=\mathrm{r}}\left(\mathrm{u}_{\mathrm{i}}^{*}-\bar{u}^{*}\right)^{2}} \tag{2.7}
\end{equation*}
$$

can be used to test (1.4) versus (1.5) rejecting the null hypothesis when an observed $Q^{*}<Q^{*}$ 。 where $Q^{*}{ }_{0}$ is a constant such that $\operatorname{Pr}\left(Q^{*}<Q^{*} 。 \mid H_{0}\right)=a$, the pre-assigned size of the test

Abrahamse and Koerst derived another estimator $W^{*}$ of U which is best in the class of all linear unbiased estimators of U. To make $\mathrm{W}^{*}$ independent of X , the authors imposed the condition that the covariance matrix of $\mathrm{W}^{*}$ is a fixed matrix F chosen a priori to be independent of X . The expression for W* is

$$
\begin{equation*}
W^{*}=\left[\mathrm{K}^{\prime} \mathrm{MK}\right]^{-1 / 2} \mathrm{~K}^{\prime} 0 \tag{2.8}
\end{equation*}
$$

where $M=I-X\left(X^{\prime} X\right)^{-1} X^{\prime}$ and $K^{\prime} K=F$.

Equation (2.8) shows that given K, or equivalently, specifying F , a corresponding $\mathrm{W}^{*}$ can be formed. The authors proved that if K is chosen to be the matrix consisting of the eigenvectors corresponding to the $n-k$ largest roots of $A_{d}$, then

$$
\mathrm{Q}^{\prime}=\frac{\underset{* * *}{\mathrm{~W}^{*}} \mathrm{~A}_{\mathrm{d}} \mathrm{~W}^{*}}{\mathrm{~W}^{*}} \mathrm{~W}^{*}
$$

$$
0
$$

has the same distribution as Durbin-Watson's upper bound du, and hence is independent of X .

Durbin proposes the following procedure as an alternative to the bounds test when the regression vectors do not coincide with the eigenvectors of $A_{d}$. Let $L$ be the matrix whose columns are the $\mathrm{k}-1$ eigenvectors of $\mathrm{A}_{\mathrm{d}}$ corresponding to the $\mathrm{k}-1$ smallest non-zero eigenvalue. Then instead of (1.3), he considered the model

$$
Y=(E|X| L)\left\{\frac{\frac{a_{1}}{A_{1}}}{\frac{A_{2}}{}}\right\}+U
$$

where $E$ is the vector with unit elements. Suppose $\hat{\mathbf{a}}_{1}, \hat{\mathbf{A}}_{2}, \mathrm{~A}_{s}$ are the least squares estimates of $a_{1}, A_{2}, A_{3}$ with

$$
\begin{aligned}
& \mathrm{V}\left(\hat{\mathbf{A}}_{1}\right)=\mathrm{s}^{2} \mathrm{G}_{1}=\mathrm{s}^{2} \mathrm{P}_{1} \mathrm{P}_{1}^{\prime}, \\
& \mathrm{V}\left(\hat{\mathbf{A}}_{1}\right)=\mathrm{s}^{2} \mathrm{G}^{2}=\mathrm{s}^{2} \mathrm{P}_{2} \mathrm{P}_{2}^{\prime}
\end{aligned}
$$

Durbin then defined the vector

$$
\Sigma=Y-\hat{a}_{1} E-X \hat{A}_{2}-L_{1} A_{3}+X_{2} A_{4}
$$

with $\mathrm{A}_{1}=\mathrm{P}_{1} \mathrm{P}_{2}{ }^{-1} \hat{\mathbf{A}}_{2} ; \mathrm{X}_{\mathrm{t}}+\mathrm{X}-\mathrm{L}\left(\mathrm{L}^{\prime} \mathrm{L}\right)^{-1} \mathrm{~L}^{\prime} \mathrm{X}$. Then he showed that the statistic

$$
d^{\prime}=\frac{\sum_{i=2}^{n}\left(z_{i}-z_{i-1}\right)^{2}}{\sum_{i=1}^{n} z_{i}{ }^{2}}
$$

has the same distribution as du whose significance points have already been tabulated since distribution is independent of X .

Koteswara Rao Kadiyala suggests three test criteria based on the estimator $W$ of $U$ which is defined as

$$
\mathrm{W}=\mathrm{P} 0
$$

Here P is a set of eigenvectors of $\mathrm{M}=\mathrm{I}-\mathrm{X}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}$ which simultaneously diagonalizes $\Sigma$, the variance-covariance matrix U under the alternative hypothesis. Like Theil's BLUS estimator, W estimates only $\mathrm{n}-\mathrm{k}$ of the components of the error vector U .

Rao's first test statistic is

$$
S_{1}=\frac{W^{\prime} D^{-1} W}{W^{\prime} W}
$$

where $D=P \Sigma P^{\prime}$ is a diagonal matrix but whose diagonal elements need not be the eigenvalues of $\Sigma$. $\mathrm{H}_{0}$ is rejected when an observed $S_{1} \leq S_{1}$, where $S_{1} 2$ is the significance point of $S_{1}$ corresponding to $\dot{\dot{L}}$, the size of the rest.

The second test procedure proposed by Rao is based on von Neuman ratio

$$
S_{2}=\frac{W^{\prime} \Delta W}{W^{\prime} W}
$$

where is the ( $n-\mathrm{k} \mathrm{n}-\mathrm{k}$ ) diagonal matrix with the non-zero characteristic roots of $A_{d}$ arranged in decreasing order of magnitude along the diagonal. The critical region is

$$
\beta_{1}=\left\{W \mid \mathbf{s}_{2} \leq S_{2} \dot{d}\right\}
$$

where $S_{2 d}$ is a constant such that $\operatorname{Pr}\left(S_{2} \leq S_{2} \dot{i}\right)=2$, the preassigned size of the test.

For his third test criterion, Rao considers two (n-k, 1) vector, $L_{1}$ and $L_{2}$ such that

$$
\begin{aligned}
& \mathrm{L}_{1} \mathrm{~L}_{2}{ }^{\prime}=\mathrm{O} ; \quad \mathrm{L}_{1}{ }^{\prime} \mathrm{L}_{1}=1=\mathrm{L}_{2}{ }^{\prime} \mathrm{L}_{2} . \\
& \beta_{5}=\left\{\mathrm{W}| | \mathrm{s}_{3} \left\lvert\,=\frac{\left|\mathrm{L}_{2}^{\prime} \mathrm{W}\right|}{\left|\mathrm{L}_{1}^{\prime} \mathrm{W}\right|} \geq \mathrm{S}_{3}\right.\right\}
\end{aligned}
$$

where $S_{3}{ }^{2}$ is determined from the equation

$$
\operatorname{Pr}\left(S_{3} \leq S_{3} \alpha \cdot \mid H_{0}\right)=\dot{x},
$$

the size of the test given in advance. $\mathrm{S}_{3}$ under $\mathrm{H}_{0}$ and $\mathrm{b}+\mathrm{dS}_{3}$ ) under $\mathrm{H}_{\mathrm{a}}$ where

$$
\mathrm{b}=\frac{\mathrm{L}_{1}^{\prime} \mathrm{DL}_{2}}{\left(\mathrm{~L}_{1}^{\prime} \mathrm{DL}_{1}\right)^{1 / 2}\left[\mathrm{LL}_{2}^{\prime} \mathrm{DL}_{2}-\frac{\left(\mathrm{L}_{1}^{\prime} \mathrm{DL}_{2}\right)^{\prime}}{\left(\mathrm{L}_{1}^{\prime} \mathrm{DL}_{1}\right)^{\prime}}\right]^{1 / 2}}
$$

and

$$
\mathrm{d}=\frac{-\left(\mathrm{L}_{1}^{\prime} \mathrm{DL}_{1}\right)^{1 / 2}}{\mathrm{~L}_{2}^{\prime} \mathrm{DL}_{2}-\frac{\left(\mathrm{L}_{1}^{\prime} \mathrm{DL}_{2}\right)^{2}}{\mathrm{~L}_{1}^{\prime} \mathrm{DL}_{1}}}
$$

both follow a cauchy distribution. Hence significance points and power of $S_{3}$ can easily be obtained.
III. Derivation of the Distribution. of Rao's Test Criterion $S_{t}$

Imhof, in his paper "Computing the Distributions of Quadratic forms in Normal Variables" [20] proved the following theorem:

Theorem 3.1. Let $Z=\left(z_{1}, \ldots, z_{m}\right)$ ' be a random vector which is normally distributed with mean 0 and covariance matrix F. Let $\mu=\left(\mu_{i}, \ldots, \mu_{m}\right)$ ' be a constant vector and consider the quadratic form:

$$
\mathrm{Q}=(\mathrm{Z}+\mu)^{\prime} \Delta(\mathrm{Z}+\mu)
$$

where $\triangle$ is a given matrix. If $F$ is non-singular, $Q$ can be written as

$$
\mathrm{Q}=\sum_{\mathrm{i}=1}^{\mathrm{m}} \delta_{\mathrm{i}} X_{\mathrm{n}_{\mathrm{ni}}} ; \lambda^{2} \mathrm{i}^{2},
$$

where
$\delta_{i}$ is a non-zero root of $F$;
$\lambda_{1}$ is a linear combination of ${ }_{1}, \ldots, m$;
$X_{{ }_{\mathrm{hi}}} ; \lambda^{2}$ is an independent chi-squarevariable with $h_{b}$ degrees of freedom and non-centrality parameter $\lambda_{1}{ }^{2}$

Then

$$
\begin{equation*}
\operatorname{Pr}(Q \geqq Z)=1 / 2+\int_{0} \frac{\sin A(r)}{r \phi(r)} d r, \tag{3.1}
\end{equation*}
$$

where

$$
\begin{aligned}
& \theta(r)=\underset{i=1}{m} \sum_{i=1}^{m}\left[h_{i} \tan ^{-1}\left(\delta_{i} r\right)+\lambda^{2} \delta_{i} \delta_{i}\left(1+\delta_{j}{ }^{2} r^{2}\right)^{-1 / 2}\right] \\
& \left.\phi(r)=\|_{i=1}^{m}\left(1+\delta_{1}^{2} r^{2}\right)^{1 / 2 h i} \quad \exp \underset{i=1}{m}\left[\lambda_{1} \delta_{j} r\right)^{2} /\left(1+\delta_{1}^{2} r^{2}\right)\right] \text {. } \\
& \lim _{r \rightarrow 0} \frac{\sin \theta(r)}{r \phi(r)}=1 / 2 \sum_{i=1}^{m} \delta_{1}\left(h_{1}+\lambda_{1}\right)^{2}-1 / 2 z \\
& \lim _{r \rightarrow \infty}\left\{\phi(r)=\left\{\left\{\begin{array}{cc}
-\infty & , \text { if } z>0 \\
\frac{\infty}{-m} \quad, & \text { if } z<0 \\
\frac{\sum}{4}=1 & h_{1} \delta_{1}\left|\delta_{1}\right|^{-1} \\
\text { if } z=0
\end{array}\right.\right.\right.
\end{aligned}
$$

Let us use above theorem to determine the cumulative distribution of Rao's $S_{1}$ (henceforth to be denoted by S), under the null hypothesis $\mathrm{H}_{0}: \overline{\mathrm{U}}$ I $\mathrm{N}(\mathrm{O}, \mathrm{I})$. We have

$$
\begin{aligned}
\operatorname{Pr}(S \leq S) & =\operatorname{Pr}\left[\frac{W^{\prime} D^{-1} W}{W^{\prime} W} \leq S\right] \\
& \left.=\operatorname{Pr}\left[\left(P^{-}\right)^{\prime} D^{-1}-S I\right)(P U) \leq 0\right] .
\end{aligned}
$$

Since $P^{\prime}\left(D^{-1}-S I\right) P$ is symmetric, then there exists am orthogonal ( $n, n$ ) matrix $H$ such that

$$
H^{\prime} \prime P^{\prime}\left(D^{-1}-S I\right) P H=\triangle
$$

or

$$
P^{\prime}\left(D^{-1}-S I\right) P=H \Delta H^{\prime}
$$

where $\Delta$ is the diagonal matrix whose elements are the eigenvalues of $\mathrm{P}^{\prime}\left(\mathrm{D}^{-1}-\mathrm{SI}\right) \mathrm{P}$. To determine these diagonal elements of $\triangle$, note that the characteristic roots of $\mathrm{P}^{\prime}\left(\mathrm{D}^{-1}-\mathrm{SI}\right) \mathrm{P}$ are equal to the roots of $\left(\mathrm{D}^{-1}-\mathrm{SI}\right) \mathrm{PP}=$ ( $D^{-1}-$ SI). Relation $\left|D^{-1}-S I-\mu I\right|=0$ implies

$$
\left|\begin{array}{cccc}
d_{1}{ }^{-1}-(S+\mu) & 0 & \cdots & 0 \\
0 & d_{2}{ }^{-1}-(S+\mu) & \cdots & 0 \\
\cdots & \cdots & \cdots & 0 \\
& & \cdots & \cdots \\
& & & \\
& & & d^{-1}-(S+\mu) \\
n-k
\end{array}\right|=0
$$

which can be written as

$$
\prod_{i=1}^{n-k}\left[d_{1}^{-1}-(S+\mu)\right]=0
$$

and therefore

$$
u_{i}=d_{i}^{-1}-S \quad(i=, \ldots, n-k)
$$

Let $\mathrm{Z}=\mathrm{H}$ ' U . Then the first two moments of Z are

$$
\begin{aligned}
\mathrm{E}(\mathrm{Z}) & =\mathrm{H}^{\prime} \mathrm{E}(0)=0 \\
& =\mathrm{H}^{\prime} \mathrm{V}(0) \mathrm{H} \\
& =\mathrm{H}^{\prime} \mathrm{IH} \\
& =\mathrm{I}
\end{aligned}
$$

Moreover, $\mathrm{Z}=\mathrm{H} \mathrm{U}$ is a linear transformation from U to Z .
Hence Z_/ $\mathrm{N}(\mathrm{O}, \mathrm{I})$. Consequently

$$
z_{1}{ }^{8} / X^{2}(1) \text { and } \underset{i=1}{n-k} z_{i}^{2} \quad \Gamma X^{2}(n-k) .
$$

We can therefore write

$$
\begin{aligned}
\operatorname{Pr}(\mathrm{S} \leq \mathrm{S}) & =\operatorname{PR}\left(\bar{U}^{\prime} \mathrm{H} \triangle H^{\prime} \overline{\mathrm{U}} \leq 0\right) \\
& =\operatorname{Pr}\left(\mathrm{Z}^{\prime} \triangle \mathrm{Z} \leq 0\right)
\end{aligned}
$$

$$
\left.=\operatorname{Pr} \sum_{[i=1}^{[n-k}\left(d_{1}{ }^{-1}-S\right) z_{1}{ }^{2}>0\right] .
$$

The assumptions of theorem 3.1 are satisfied by i-1
$\sum_{i=1}\left(d_{i}{ }^{-1}-S\right) z_{i}{ }^{2}$ playing the role of $Q$ with $m=n-k, F=I$, $d_{i}=\left(d_{i}^{-1}-S\right) h_{i}=1$ and $\lambda_{1}=0$. Therefore by using (3.1) we obtain the following expression for the cumulative distribution of S under $\mathrm{H}_{0}$, i.e.

$$
\begin{equation*}
\operatorname{Pr}(S \leq S)=1-\left(1 / 2+\frac{1}{\pi} \int_{0} \frac{\sin \theta(r)}{r \theta(r)} d r\right) \tag{3.2}
\end{equation*}
$$

where

$$
\begin{aligned}
& \theta(r)=1 / 2 \sum_{i=1}^{n-k} \tan ^{-1}\left[\left(d_{1}^{-1}-S\right) r\right] . \\
& \phi(r)={\underset{i}{ }=1}_{\pi-k}^{\pi}\left[1+\left(\mathrm{d}_{1-1}^{-1}-\mathrm{S}\right)^{2} \mathrm{r}^{2}\right]^{1 / 4}, \\
& \lim _{r \rightarrow 0} \frac{\sin \theta(r)}{r \ddot{\phi}(r)}=1 / 2 \sum_{i=1}^{n-k}\left(d_{1}^{-1}-S\right), \\
& \lim _{r \rightarrow \infty}[\theta(r)]=\frac{\pi}{4} \sum_{i=1}^{n-k}\left(d_{1}{ }^{-1}-S\right)\left|d_{i}{ }^{-1}-S\right|^{-1} .
\end{aligned}
$$

Under the alternative hypothesis $\mathrm{H}_{\mathrm{a}}$, we have

$$
\begin{aligned}
& \mathrm{E}(\mathrm{U})=0 \\
& \mathrm{~V}(\mathbb{0})=\mathrm{\Sigma} .
\end{aligned}
$$

Since $\Sigma$ is positive definite, there exists a non-singular matrix $C$ such that

$$
\begin{equation*}
\Sigma=\mathrm{CC}^{\prime} \tag{3.3}
\end{equation*}
$$

Let us now derive the cumulative distribution function: of S under $\mathrm{H}_{2}$. We have

$$
\begin{aligned}
\operatorname{Pr}(S \leq S) & =\operatorname{Pr}\left[\frac{\left[W^{\prime} D^{-1} W\right.}{\left[W^{\prime} W-\right.} \leq S\right] \\
& =\operatorname{Pr}\left[W^{\prime}\left(D^{-1}-S I\right) W \leq 0\right] \\
& =\operatorname{Pr}\left[U^{\prime} P^{\prime}\left(D^{-1}-S I\right) \operatorname{PO} \leq 0\right]
\end{aligned}
$$

Now, let $V=C^{-1} \mathrm{U}$, where C is defined as in (3.3). Then $\mathrm{U}=\mathrm{CV}$ so that when $\mathrm{H}_{\mathrm{a}}$ is true, we obtain

$$
\begin{align*}
\mathrm{E}(\mathrm{~V}) & =\mathrm{C}^{-1} \mathrm{E}(\bar{U})=0 \\
\mathrm{~V}(\mathrm{~V}) & =\mathrm{C}^{-1} \mathrm{~V}(\tilde{U})\left(\mathrm{C}^{\prime}\right)^{-1} \\
& =\mathrm{C}^{-1} \Sigma\left(\mathrm{C}^{\prime}\right)^{-1} \\
& =\mathrm{C}^{-1} \mathrm{CC}^{\prime}\left(\mathrm{C}^{\prime}\right)^{-1} \\
& =\mathrm{I} . \tag{3.4}
\end{align*}
$$

Therefore

$$
\operatorname{Pr}(S \leq S)=\operatorname{Pr}\left(V^{\prime} C^{\prime} P^{\prime}\left(D^{-1}-S I\right) \operatorname{PCV} \leq 0\right)
$$

It can easily be seen that C'P' ( $\mathrm{D}^{-1}-\mathrm{SI}$ ) PC is a symmetric matrix. Moreover, its eigenvalues are the characteristic roots of

$$
\begin{aligned}
\left(\mathrm{D}^{-1}-\mathrm{SI}\right) P C C^{\prime} \mathrm{P}^{\prime} & =\left(\mathrm{D}^{-1}-\mathrm{SI}\right) \underset{\mathrm{P}}{ } \mathrm{\Sigma} \mathrm{P}^{\prime} \\
& =\left(\mathrm{D}^{-1}-\mathrm{SI}\right) \mathrm{D} \\
& =(\mathrm{I}-\mathrm{SD}) .
\end{aligned}
$$

But $|I-S D-\lambda I|=0$ implies $|(1-\lambda) I-S D|=0$, n-k
which imples $\pi\left(1-\lambda-S d_{1}\right)=0$. Consequently, the cha$\mathrm{i}=1$
racteristic roots of $I-S D$ are

$$
\begin{equation*}
\lambda_{1}=1-\operatorname{Sd}_{\mathrm{i}} \quad(\mathrm{i}=1 \ldots, \mathrm{n}-\mathrm{k}) \tag{3.5}
\end{equation*}
$$

Above statements imply that there is an orthogonal matrix G such that G[C'P' ( $\left.\left.D^{-1}-S I\right) P C\right] G^{\prime}=\Omega$ Where $/ \Omega$ is a diagonal matrix whose diagonal elements are the $\lambda_{i}$ 's defined in (3.5). Thus, we have

$$
\operatorname{Pr}(S \leq S)=\operatorname{Pr}\left(V^{\prime} G^{\prime} \quad \cap G V \leq 0\right.
$$

$$
\begin{aligned}
& \theta(r)=\frac{\mathrm{n}-\mathrm{k}}{\mathrm{i}=1}\left[1+\left(1-S d_{i}\right)^{2} r^{2}\right]^{1 / 4}, \\
& \lim \frac{\sin \theta(r)}{r \phi(r)}=1 / 2 \sum_{i=1}^{n-k}\left(1-S d_{i}\right) .
\end{aligned}
$$

Note that the distributions of S both under the null and the null and the alternative hypothesis depend on $d_{1}$, the elements of $\mathrm{D}=\mathrm{P} \Sigma \mathrm{P}$, which in turn is dependent on X through P. Hence the significance points and power of $S$ can be determined only for a given matrix X .

## IV. Application

Let us consider the example of the consumption of textile in the Netherlands. The data is tabulated below

TABLE I
TIME SERIES FOR THE TEXTILE EXAMPLE

| Year | y | $\mathrm{x}_{2}$ | $\mathrm{x}_{3}$ |
| :---: | :---: | :---: | :---: |
| 1923 | 1.99651 | 1.98543 | 2.00432 |
| 1924 | 1.99564 | 1.99167 | 2.00043 |
| 1925 | 2.00000 | 2.00000 | 2.00000 |
| 1926 | 2.04766 | 2.02078 | 1.95713 |
| 1927 | 2.08797 | 2.02078 | 1.93702 |
| 1928 | 2.07041 | 2.03941 | 1.95279 |
| 1929 | 2.08314 | 2.04454 | 1.95713 |
| 1930 | 2.13354 | 2.05038 | 1.91803 |
| 1931 | 2.18808 | 2.03862 | 1.84572 |
| 1932 | 2.18639 | 2.02243 | 1.81558 |
| 1933 | 2.20003 | 2.00732 | 1.78746 |
| 1934 | 2.14799 | 1.97955 | 1.79588 |
| 1935 | 2.13418 | 1.98408 | 1.80346 |
| 1936 | 2.22531 | 1.98945 | 1.72099 |
| 1937 | 2.18837 | 2.01030 | 1.77597 |
| 1938 | 2.17319 | 2.00689 | 1.77452 |
| 1939 | 2.21880 | 2.01620 | 1.78746 |

To simplify further above expression, let

$$
\mathrm{Z}=\mathrm{GV}
$$

Then from relation (3.4) we have

$$
\begin{aligned}
\mathrm{E}(\mathrm{Z}) & =\mathrm{GE}(\mathrm{~V})=0 \\
\mathrm{~V}(\mathrm{Z}) & =\mathrm{GV}(\mathrm{~V}) \mathrm{G}^{\prime} \\
& =\mathrm{GI} \mathrm{G}^{\prime} \\
& =\mathrm{I} .
\end{aligned}
$$

This means that $\sum_{i=1}^{n-k} z_{i}{ }^{2}$ is a central chi-square variable with
n-k degrees of freedom. Therefore

$$
\begin{aligned}
\operatorname{Pr}(S \leq S) & =\operatorname{Pr}\left(Z^{\prime} \cap Z \leq 0\right) \\
& \left.=\underset{i=1}{\operatorname{Pr}(k} \Sigma \lambda_{i} z_{i}^{2} \leq 0\right) \\
& =1-\underset{i=1}{\left.\operatorname{Pr} \sum\left(1-S d_{1}\right) z_{1}{ }^{2}>0\right)} .
\end{aligned}
$$

Since the assumptions of theorem 3.1 are satisfied by n-k
$\Sigma\left(1-S d_{i}\right) z_{1}{ }^{2}$, playing the role of $Q$, then the cumulative $\mathrm{i}=1$
density function of $S$ under $H_{a}$ is of the form:

$$
\begin{align*}
\operatorname{Pr}(\mathrm{S} \leq \mathrm{S}) & =1-\left(1 / 2+\frac{1}{\pi} \int_{0}^{\infty} \frac{\sin \theta(r)}{r \phi(r)} d r\right) \\
& =1 / 2-\frac{1}{\pi} \int_{0}^{\infty} \frac{\sin \theta(r)}{r_{\phi}(r)} d r, \tag{3.6}
\end{align*}
$$

where

$$
\theta(r)=1 / 2 \sum_{1=1}^{n-k} \tan ^{-1}\left[\left(1-S d_{1}\right) r\right],
$$

$\mathrm{y}=$ logarithm of per capita consumption of textile, obtained by dividing the money value of textile consumption by family households by PN.
$\mathrm{p}=$ retail price index of clothing for the city of Amsterdam
$\mathrm{N}=$ population of the Netherlands
$\mathrm{X}_{1}=$ logarithm of real per capita income, obtained by dividing the money value of income of family households by N
$\pi=$ general retail price index
$\mathrm{X}_{2}=$ logarithm of the deflated price index of clothing, i.e., of the ratio $\mathrm{P} / \pi$.

Rao's test criterion $S_{1}$ was applied to this example. Here we have

$$
\mathbf{Y}=\left\{\begin{array}{l}
1.99651  \tag{4.1}\\
1.99564 \\
2.00000 \\
2.04766 \\
2.08707 \\
2.07041 \\
2.08314 \\
2.13354 \\
2.18808 \\
2.18639 \\
2.20003 \\
2.14799 \\
2.13418 \\
2.22531 \\
2.18837 \\
2.17319 \\
2.21880
\end{array}\right\}, \mathrm{X}=\left\{\begin{array}{llll}
1.00000 & 1.98543 & 2.00432 \\
1.00000 & 1.99167 & 2.00043 \\
1.00000 & 2.00000 & 2.00000 \\
1.00000 & 2.02078 & 1.95713 \\
1.00000 & 2.02078 & 1.93702 \\
1.0000 & 2.03941 & 1.95279 \\
1.00000 & 2.04454 & 1.95713 \\
1.00000 & 2.05038 & 1.91803 \\
1.00000 & 2.03862 & 1.84572 \\
1.00000 & 2.02243 & 1.81558 \\
1.0000 & 2.00732 & 1.78746 \\
1.00000 & 1.97955 & 1.79588 \\
1.00000 & 1.98408 & 1.80346 \\
1.00000 & 1.98945 & 1.72099 \\
1.00000 & 2.01030 & 1.77597 \\
1.00000 & 2.0689 & 1.77452 \\
1.00000 & 2.01620 & 1.78746
\end{array}\right\}
$$

We would like to test the null hypothesis

$$
\begin{equation*}
\mathrm{H}_{\mathrm{o}}: \overline{\mathrm{U}} I \mathrm{~N}(\mathrm{O}, \mathrm{I}) \tag{4.2}
\end{equation*}
$$

against the alternative hypothesis that $\mathrm{U}_{1}$ follow a stationary Markoff scheme (see equation (2.4) ), with correlation coefficient $P=.8$. That is

$$
\mathrm{H}_{\star}: \overline{\mathrm{U}} / \mathrm{I}^{\mathrm{N}}(0, \Sigma)
$$

where
$\left.\leq=\frac{1}{1-(.8)^{2}}\left\{\begin{array}{ccccc}1 & .8 & (.8)^{2} & \ldots & (.8)^{16} \\ .8 & 1 & .8 & \ldots & (.8)^{15} \\ \ldots & \ldots & \ldots & \ldots & \ldots\end{array}\right] ..\right\}$
First, let us find the matrix $P$ of the transformation $\mathrm{W}=\mathrm{PO}$. In section II, P was defined as a ( $\mathrm{n}-\mathrm{k}, \mathrm{n}$ ) row-orthogonal matrix whose rows form a set of eigenvectors of $\mathrm{M}=\mathrm{I}-$ $\mathrm{X}\left(\mathrm{X}^{\prime} \mathrm{X}\right)^{-1} \mathrm{X}^{\prime}$ corresponding' to the eigenvalue one; and which simultaneously diagonilizes $\Sigma$, the variance-covariance matrix of $U$ under $H_{a}$.

Since for any X of rank $\mathrm{k}, \mathrm{M}$ is a symmetric, idempotent matrix of rank $n-k$, there exists an orthogonal matrix $R$ such that

$$
R_{M R}{ }^{\prime}=\left\{\begin{array}{l|l}
\mathrm{I}_{\mathrm{n}-\mathrm{k}} & 0  \tag{4.4}\\
\hline 0 & 0_{\mathrm{k}}
\end{array}\right\}
$$

Such an $R$ was found using the SSP program EIGEN. Let us partition R into

$$
R=\left\{\frac{R_{1}}{R_{2}}\right\}
$$

where $R_{1}$ is (14, 17). Then (4.4) implies that $R_{1}$ form a set set of eigenvectors of $M$ corresponding to the eigenvalue one.

Next we define $K=R_{1} \Sigma R_{1}{ }^{\prime}$. Since $K$ is symmetric, there exists an orthogonal $(14,14)$ matrix $T$ (such a $T$ can be found using SSP program EIGEN) such that

$$
\mathrm{TKT}^{\prime}=\mathrm{TR}_{1} \Sigma \mathrm{R}_{1}{ }^{\prime} \mathrm{T}^{\prime}=\mathrm{D}
$$

where D is a diagonal matrix whose non-zero elements are the eigenvalues of $K$. We have

$$
\mathrm{D}=\left\{\begin{array}{cccccccccccccc}
.312 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & .348 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0.355 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0.383 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & .403 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0.468 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0.515 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0.565 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0.697 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0.892 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1.192 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1.654 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 2.225 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 4.832
\end{array}\right\}
$$

Let

$$
\begin{aligned}
\mathrm{P} & =\mathrm{TR}_{1} . \quad \text { Then } \\
\mathrm{PMP}^{\prime} & =\mathrm{TR}_{1} \mathrm{MR}_{1}{ }^{\prime} \mathrm{T}^{\prime} \\
& =\mathrm{T}_{15}
\end{aligned}
$$

Hence $P$ satisfies the conditions imposed on the matrix of the transformation $\mathrm{W}=\mathrm{PU}$. Carrying out the matrix multiplication, we obtain

$$
\left\{\begin{array}{rrrrrrrrr}
0.0207 & -0.0724 & 0.1190 & -0.1802 & 0.2468 & -0.2982 & 0.3366 & -0.3746 & 0.3914 \\

& -0.1745 & -0.1239 & 0.1730 & 0.2710 & -0.1729 & -0.0649 & 0.0091 & 0.1241 \\
-0.0105 & -0.1164 & -0.1239 & -0.1306 & 0.0938 & 0.2072 & 0.1406 & -0.1382 & -0.2665 \\
& -0.0447 & 0.2248 & 0.3732 & 0.0310 & -0.4842 & -0.3568 & 0.1313 & 0.4693 \\
-0.1686 & 0.0343 & 0.2282 & 0.4122 & 0.2133 & -0.1835 & -0.4443 & -0.2688 & 0.1469 \\
& 0.3323 & 0.2696 & -0.1164 & -0.3584 & -0.1173 & 0.1386 & 0.0209 & 0.1415 \\
-0.3970 & -0.2379 & 0.0448 & 0.3296 & 0.4719 & 0.3165 & 0.0447 & -0.2017 & -0.2740 \\
& -0.2292 & -0.0672 & 0.1202 & 0.1887 & 0.2379 & 0.0135 & -0.1246 & -0.2338 \\
0.0366 & 0.0548 & 0.0674 & 0.1042 & 0.0442 & 0.0316 & -0.0429 & -0.1161 & -0.2351 \\
& -0.3206 & -0.3564 & -0.3557 & -0.1725 & 0.0487 & 0.3115 & 0.4236 & 0.4860 \\
& & & & & & & &
\end{array}\right\}
$$

## The relation $W=P \mathbb{C}$ can be simplified into

$$
\begin{aligned}
& =\mathrm{P}\left[\mathbf{Y}-\mathrm{X}\left(\mathrm{X}^{\prime} \mathbf{X}\right)^{-1} \mathrm{X}^{\prime} \mathrm{Y}\right] \\
& =\mathrm{P} \mathbf{M} \mathbf{Y}=\mathbf{P} \mathbf{Y}
\end{aligned}
$$

Using the above equation the obtain the following form for $W$ by multiplying the matrix $P$ given by (4.5) and the vector $Y$ given by (4.1). We have

$$
\mathrm{W}=\left\{\begin{array}{r}
.02430 \\
-.29779 \\
-.17810 \\
-.39676 \\
-.22469 \\
.47677 \\
-.45960 \\
.57347 \\
.31691 \\
1.00539 \\
.02746 \\
.37536 \\
.83127 \\
-.08035
\end{array}\right\}
$$

We are now ready to compute the test statistic $S$. We have

$$
\mathrm{S}=\frac{\mathrm{W}^{\prime} \mathrm{D}^{-1} \mathrm{~W}}{\mathrm{~W}^{\prime} \mathrm{W}}=\frac{\sum_{\mathrm{i}=1}^{15} \mathrm{~d}_{1}^{-1} \mathrm{~W}_{i^{2}}}{\sum_{\mathrm{i}=1}^{15} \mathrm{~W}_{\mathrm{i}}^{2}}=.329
$$

Table II, next page, gives the $\operatorname{Pr}\left(S \leq S \mid H_{0}\right)$ and $\operatorname{Pr}\left(\mathrm{S} \leq \mathrm{S} \mid \mathrm{H}_{1}\right)$ for selected values of S . Table II was obtained using formulas (3.2) and 3.6) where the integral

## $\infty \sin \theta(r)$

$\int_{0} \frac{}{r_{\phi^{(r)}}} \mathrm{dr}$ was approximated using the SSP QSF. From this table, we can see that Ho is rejected for $\alpha=.055$.

## TABLE II

| S | $\operatorname{Pr}\left(\mathrm{S} \leq \mathrm{SH}_{0}\right)$ | $\operatorname{Pr}(\mathrm{S} \leq \mathrm{S} \mathrm{H})$ |
| :---: | :---: | :---: |
| .1 | .000008 | .000006 |
| .2 | .000010 | .000013 |
| .3 | .000011 | .000455 |
| .4 | .000013 | .009166 |
| .5 | .000027 | .037201 |
| .6 | .000110 | .087500 |
| .7 | .000410 | .159454 |
| .8 | .001800 | .249752 |
| .9 | .005290 | .352139 |
| 1.0 | .013152 | .458964 |
| 1.1 | .028482 | .563044 |
| 1.2 | .055004 | .658782 |
| 1.3 | .096448 | .742552 |
| 1.4 | .155667 | .812595 |
| 1.5 | .233693 | .868682 |
| 1.6 | .329014 | .911720 |
| 1.7 | .437210 | .943309 |
| 1.8 | .551321 | .965419 |
| 1.9 | .662868 | .980093 |
| 2.0 | .763482 | .989279 |
| 2.1 | .846733 | .994656 |
| 2.2 | .909473 | .997578 |
| 2.3 | .952071 | .999029 |
| 2.4 | .977718 | .999682 |
| 2.5 | .991116 | .999936 |
| 2.6 | .997033 | .999968 |
| 2.7 | .999187 |  |
| 2.8 | .999819 |  |
| 2.9 |  |  |
| 3.0 |  |  |
|  |  |  |

The null hypothesis (4.2) was tested against the alternative (4.3) for the same textile example, using the BLUS procedure with the last three components of $U$ not estimated. Computing for the von Neuman of $\mathrm{U}^{*}$ which was defined as

$$
Q^{*}=\frac{\sum_{i=2}^{14}\left(u_{1}^{*}-u_{i-1}^{*}\right)^{2}}{\sum_{i=1}^{\sum}\left(u_{1}^{*}-\bar{u}^{*}\right)^{2}}
$$

we obtain $Q^{*}=.85 t ; 72$.
For a $5 \%$ level of significance, the critical region is $Q^{*}<1.1276$. This is taken from a table of significance points of $Q^{*}$ tabulated by Abrahamse and Koerts [1]. Hence Ho is rejected.

Theil and Nagar [26] computed for the value of DurbinWatson's test statistic $d$ for the textile example and found it to be equal to $\mathrm{d}=1926$. We were able to determine the $\operatorname{Pr}(d \leq d \mid H o)$ and $\operatorname{Pr}\left(d \leq \mid H_{1}\right)$ for the textile example, using the Imhof theorem, theorem 3.1. Using these significance points, $H_{0}$ is not rejected at $4.1 \%$ level of significance.

The following table summarizes the above results.

## TABLE III

Testing the Independence of the Regression Errors for the Textile Example Using Test Statistics $S_{1} Q^{2}$ and d.

| Rao's S | Theil's $\mathrm{Q}^{*}$ |  | Durbin-Watson d |  |
| :---: | :---: | :---: | :---: | :---: |
| 2 Conclusion | 2 | Conclusion | 2 |  |
| .$^{.055} \begin{gathered}\text { Hot Rejected } \\ \text { Rod }\end{gathered}$ | . 05 | $\mathrm{H}_{\mathrm{o}}$ <br> Rejected | . 041 | $\underset{\substack{\mathrm{H}_{\mathrm{o}} \\ \text { Reject }}}{ }$ |

The power of a test is defined as the probability that the alternative hypothesis is accepted when it is true. Using this definition we were able to compute the powers of $S$ and $d$ for the textile example from the tabulated values of $\operatorname{Pr}\left(\mathrm{S} \leq \mathrm{S} \mid \mathrm{H}_{1}\right)$ and $\operatorname{Pr}\left(\mathrm{d} \leq \mathrm{d} \mid \mathrm{H}_{1}\right)$. The power of the BLUS test was computed by Abrahamse and Koerst [1].

Below is a comparison of the power of $S$ with the powers of $d$ and $Q^{*}$

## TABLE IV

Powers of S, Q, d for the Textile Example

| Rao's S |  | Theil's $\mathrm{Q}^{*}$ |  | Durbin-Watson's d |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\pm$ | Power | 2 | Power | 2 | Power |
| . 055 | . 659 | . 05 | . 36 | . 041 | . 676 |

To check the cumulative distribution of S derived in Section III, the emperical distributions of this statistic under both the null and the alternative hypothesis were constructed using Monte Carlo procedure. The observed frequencies were then compared with the corresponding theoretical frequencies as computed from table II, by means of the chi-square test. For a $5 \%$ level of significance, we conclude that the fit is good.
