# SOME TESTS FOR A SHIFT IN THE MEAN OF A NORMAL DISTRIBUTION OCCURRING AT UNKNOWN TIME POINTS 

H. F. Magalit and L. D. Broemeling

## 1. Background

Detecting a change in the mean of a sequence of independent normally distributed observations, when the time the change occurs is unknown, is an important statistical problem and has been considered by Vage (1955) and Bhatcharayya and Johnson (1968) using non-parametric procedures, while Chernoff and Zacks (1966), Kander and Zacks (1966), and Mustafi (1968) developed a Bayesian approach. Cox (1961), considered the problem as an example for separate families of hypotheses.

By assuming the time when the change occurs as known and constructing the corresponding likelihood-ratio test for a change in the mean, then averaging the test statistics over all possible shift points, the resulting statistic is used to detect a shift in the mean, when the time the change occurs is unknown. The critical region and power function of the test is derived for one and two-sided alternatives. If a change occurs, it is assumed that it occurs only once.

Consider a test of

$$
\begin{aligned}
& \mathrm{H}_{0}: \mathrm{X}_{1}, \mathrm{X}_{2}, \ldots, \mathrm{X}_{\mathrm{n}} \sim \operatorname{nid}\left(\theta_{0}, \sigma^{2}\right) \\
& \mathrm{H}_{1}: \mathrm{X}_{1}, \mathrm{X}_{2}, \ldots, \mathrm{X}_{\mathrm{m}} \sim \operatorname{nid}\left(\theta_{0}, \sigma^{2}\right) \\
& \mathrm{X}_{\mathrm{n} 1}+1, \ldots, \mathrm{X}_{\mathrm{n}} \sim \operatorname{nid}\left(\theta_{1}, \sigma^{2}\right)
\end{aligned}
$$

where $\sigma^{2}$ is the known common variance of the observations, $\theta_{1}$ and $m(1 \leq m \leq n-1)$ are unknown, but $\theta_{0}$ may be either known or not. $\theta_{0}$ is inferred to as initial mean and $m$ the shift point. If ${\hat{\hat{v}_{1}}}_{1}>\theta_{1}, H_{1}$ is a one-sided alternative and if $\theta_{1} \div \theta_{0}$ a two-sided one. For convenience we let $\sigma^{2}=1$.
2. One-sided alternative, $\theta_{1}>\theta_{0}$.

Considering $\theta_{0}$ as known, and the shift point at $m=s$, the LRT of

$$
\begin{aligned}
& H_{0 s}: X_{s}+1, \ldots, X_{n} \sim n\left(\theta_{0}, 1\right) \\
& H_{1 s}: X_{s}+1, \ldots, X_{n} \sim n\left(\theta_{0}, 1\right)
\end{aligned}(s=1,2, \ldots, n-1)
$$

leads to the test statistic

$$
\lambda^{(s)}=(n-s)^{-1 / 2}\left(\bar{X}_{s+1, n}-\theta_{0}\right)(s=1,2 \ldots, n-1)
$$

where $\overline{\mathbf{X}}_{\mathrm{s}-1-1, \mathrm{n}}$ is the mean of the last ( $\mathrm{n}-\mathrm{s}$ ) observations, and $\mathrm{H}_{0 \mathrm{~s}}$ is rejected for large values. Averaging the $\lambda^{(8)}$ over the possible shift points, we have (neglecting a divisor of ( $\mathrm{n}-1$ ) )

$$
\begin{align*}
T^{(1)} & =\sum_{s=1}^{n-1} \lambda^{(s)}  \tag{2.1}\\
& =\sum_{i=2}^{n}\left[\sum_{j=1}^{\sum=1-1}(n-j)^{-1 / 2}\right] \quad\left(x_{i} \theta_{0}\right),
\end{align*}
$$

and $H_{0}$ is rejected with a type I error of $a$ whenever $T^{(1)} \geq$ $\mathrm{K}^{(1)}(\mathrm{a})$, where

$$
a=P\left[T^{(1)} \geq K^{(1)}(a) \mid H_{0}\right] .
$$

It is easy to verify that the distribution of $\mathrm{T}^{(1)}$ under $\mathrm{H}_{0}$ is normal with mean 0 and variance

$$
\operatorname{Var}\left[T^{(1)} \mid H_{0}\right]=\sum_{i=2}^{n}\left[\sum_{j=1}^{j=i-1}(n-j)^{-1 / 2}\right]^{2}
$$

and under $\mathrm{H}_{1}$ with mean
$\left.\mu^{(1)}\left(m, \theta_{1}\right) \underset{i=m+1}{\sum_{j=1}^{n}\left[\sum^{i-1}(n-j)^{-1 / 2}\right]}\left(\theta_{1}-\theta_{0}\right) \quad m=1,2, \ldots n-1 \quad \theta_{1}>\theta_{0}\right)$.
and variance $\operatorname{Var}\left[\mathrm{T}^{(10} \mid \mathrm{H}_{0}\right]$.
Since $Z^{(1)}=\left[T^{(1)}-\mu^{(1)}\left(m, \theta_{1}\right)\right] / \sigma\left(T^{(1)}\right)$ is distributed as $\boldsymbol{a}$
standard normal, $\mathrm{H}_{0}$ is rejected whenever

$$
\begin{equation*}
\mathrm{Z}^{(1)} \geq \mathrm{Z}_{\alpha} \tag{2.2}
\end{equation*}
$$

and the power of the test when $m$ and $\ell_{1}$ are the shift point and new mean is

$$
\begin{equation*}
\beta_{\mathrm{m}}{ }^{(1)}\left(\theta_{1}\right)=\mathrm{P}\left[\mathrm{Z} \geq \mathrm{z}_{\alpha}-\mu^{(1)}\left(\mathrm{m}, \hat{U}_{1}\right) / \sigma\left(\mathrm{T}^{(1, p}\right)\right], \tag{2.3}
\end{equation*}
$$

where $z_{a}$ is the upper $100 a$ percent point of $n(0,1)$ and $\sigma\left(T^{(1)}\right)$ is the standard deviation of $\mathrm{T}^{(1)}$.

If the initial mean is unknown, a size 2 test of $H_{\circ}$ versus $\mathrm{H}_{1}$ is to reject $\mathrm{H}_{0}$ whenever

$$
Z^{(\otimes)} \geq z_{\alpha}
$$

where

$$
Z^{(2)}=\left[T^{(2)}-\mu^{(2)}\left(m, \hat{\theta}_{0}, \theta_{1}\right)\right] / \sigma\left(T^{(2)}\right)
$$

with

$$
\begin{align*}
T^{(2)} & \left.=\underset{s-1}{n-1} \bar{X}_{s-1-1, n}-\bar{X}_{1, s}\right)[s(n-s) / n]^{1 / 2} \\
& \left.=\sum_{i=1}^{n}\left[\sum_{j=1}^{i-1}(j / n(n-j)) \underset{j=i}{n-1}(n-j) / n j\right)\right] x_{i}, \tag{2.4.}
\end{align*}
$$

and $\mu^{(2)}\left(\mathrm{m}, \hat{\mathrm{v}}_{0}, €_{1}\right)$ and $\sigma\left(\mathrm{T}^{(2)}\right)$ are the mean and standard deviation of $\mathrm{T}^{121}$. The power of the test for the alternative ( $m, \hat{\varepsilon}_{0}, \hat{f}_{1}$ ) is

$$
\beta_{\mathrm{m}}^{(2)}\left(\hat{ज}_{0}, \hat{龴}_{1}\right)=\mathrm{P}\left[\mathrm{Z}^{(2)} \geq \mathrm{za}-\mu^{(2)}\left(\mathrm{m}, \hat{\hat{V}}_{0}, \hat{\cap}_{1}\right) / \sigma\left(\mathrm{T}^{(2)}\right)\right.
$$

Tables I and II are tabulations of the power of the tests based on $\mathrm{T}^{(1)}$ and $\mathrm{T}^{(2)}$ respectively for a size $a=.05, \mathrm{n}=12$, $\mathrm{m}=1,3, \ldots, 11, \hat{\epsilon}_{0}=0, \sigma^{2}=1$, and $\hat{\vartheta}_{1}=3, .6, .9, \ldots, 1.2$. The power of the Bayes' procedure, chernoff and Zacks (1964), is also tabulated and we see that when $\theta_{0}$ is know $T^{(1)}$ has higher power if the change occurs early ( $1 \leq m \leq 3$ ).

The tests based on $T^{(1)}$ and $T^{(2)}$ are unbiased, because $\mu^{(1)}\left(\mathrm{m}, \hat{\sigma}_{1}\right)$ and $\mu^{(2)}\left(\mathrm{m}, \hat{\mathrm{U}}_{0}, \hat{U}_{1}\right)$ are non-negative for $\hat{च}_{1}>\theta_{0}$ and shifts $m=1,2, \ldots, n-1$.
3. Twó-sided alternatives, $\theta_{1} \doteqdot \theta_{0}$.

When we consider the two-sided alternative, the non-null distribution of the test statistics ( $\mathrm{T}^{(3)}$ and $\mathrm{T}^{(4)}$, corresponding to $\hat{\hat{v}_{0}}$ known and unknown, is approximated by equating their first two moments to a weighted chi-square $a x^{2}(\mathrm{~b})$ and solving for a and b . . Thus the approximate power of the tests are found by interpolating the central chi-square tables or by integrating the gamma density.

If $€_{0}$ is known the likelihood-ratio statistic of $\mathrm{H}_{0 \mathrm{~s}}$ versus $\mathrm{H}_{\mathrm{si}}(\mathrm{s}=1,2, \ldots, \mathrm{n}-1)$ is $\mathrm{r}^{(\mathrm{s})}=(\mathrm{n}-\mathrm{s})\left(\mathrm{X}_{\mathrm{s}}+_{1, \mathrm{n}}-\theta_{0}\right)^{2}$ and averaging over the shift points gives

$$
\begin{equation*}
\mathrm{T}^{(3)}=\Sigma(\mathrm{n}-\mathrm{s})\left(\mathrm{X}_{\mathrm{s}-\mid-1, \mathrm{n}}-\hat{\mathrm{V}}_{0}\right)^{2}, \tag{3.1}
\end{equation*}
$$

a sum of correlated chi-square statistics each with one dif. Letting

$$
\begin{aligned}
& \mathrm{E}\left[\ddot{\mathrm{~T}}^{(3)} \mid \mathrm{H}_{0}\right]=\mathrm{a}_{0} \mathrm{~b}_{0} \\
& \operatorname{Var}\left[\mathrm{~T}^{\left({ }^{3}\right)} \mid \mathrm{H}_{0}\right]=2 \mathrm{a}^{2}{ }_{0} \mathrm{~b}
\end{aligned}
$$

and solving for $a_{0}$ and $b_{0}$, we have $a_{0}=n / 2$ and $b_{0}=2(n-1) / n$, and $\mathrm{H}_{0}$ is rejected whenever

$$
\begin{equation*}
T^{(3)} \geq a_{0} x_{2^{2}}\left(b_{0}\right) \tag{3.2}
\end{equation*}
$$

where $x_{\alpha^{2}}\left(\mathrm{~b}_{0}\right)$ is the upper $100{ }^{2}$ percent point of the $x^{2}$ distribution with $b_{0}$ d.f. The approximate power of the test, for all $m=1,2, \ldots, n-1$ and $f_{1}$, is

$$
\beta_{\mathrm{m}}^{(3)}\left(\theta_{1}\right)=\mathrm{P}\left[\mathrm{~T}^{(3)} \geq \mathrm{a}_{0} x_{\alpha^{2}}\left(\mathrm{~b}_{0}\right) \mid\left(\mathrm{m}, \hat{\theta}_{1}\right)\right] .
$$

The distribution of $T^{(3)}$ for given alternative ( $m, \theta_{1}$ ) is found the same way as above by solving

$$
\begin{equation*}
\mathrm{E}\left[\mathrm{~T}^{(3)} \mid\left(\mathrm{m}, \hat{\mathrm{v}}_{1}\right)\right]=\mathrm{a}\left(\mathrm{~m}, \theta_{1}\right) \mathrm{b}\left(\mathrm{~m}, \hat{\mathrm{v}}_{1}\right) \tag{3.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\operatorname{Var}\left[T^{(3)} \mid\left(m, \hat{v}_{1}\right)\right]=2 a^{2}\left(m . \theta_{1}\right) b\left(m, \cdot \hat{\theta}_{1}\right) \tag{3.4}
\end{equation*}
$$

for $a\left(m, \theta_{1}\right)$ and $b\left(m, \theta_{1}\right)$, and using

$$
\begin{equation*}
\beta_{\mathrm{m}}{ }^{(3)}\left(\theta_{1}\right)=\mathrm{P}\left[\mathrm{a}\left(\mathrm{~m}, \hat{\mathrm{~V}}_{1}\right) x^{2}\left[\mathrm{~b}\left(\mathrm{~m}, \theta_{1}\right)\right] \geq \mathrm{a}_{0} x_{a^{2}}\left(\mathrm{~b}_{0}\right)\right] \tag{3.5}
\end{equation*}
$$

for the power of the size a test based on $\mathrm{A}^{(3)}$ (3.2). (3.3) and (3.4) are easily solved by using the fact that

$$
\begin{align*}
E\left[T^{(3)} \mid\left(m, \theta_{1}\right)\right] & =\sum_{\mathrm{S}=1}^{\mathrm{n}-1} \mathrm{E}\left(\mathrm{X}^{\prime} \mathrm{A}_{\mathrm{s}} \mathrm{X}\right) \\
& =\sum_{\mathrm{s}=1}^{\mathrm{n}-1} \mathrm{~T}_{\mathrm{r}}\left(\mathrm{~A}_{\mathrm{s}}\right)+\underset{\mathrm{S}=1}{\mathrm{n}-1} \mu^{\prime} \mathrm{A}_{\mathrm{s}} \mathbf{u} \tag{3.6}
\end{align*}
$$

where $T_{r}$ is the trace of a matrix and

$$
\operatorname{Var}\left[T^{(s)} \mid\left(m, \theta_{1}\right)\right] \underset{s=1}{n-1} \operatorname{Var}\left(X, A_{s} X\right)+\underset{s<t}{2 \Sigma \Sigma \operatorname{cov}} \quad\left(X^{\prime} A_{s} X, X^{\prime} A_{t} X\right)
$$

where $\left.(n-s) X_{8-1-1, n}-\theta_{0}\right)^{2}=X^{\prime} A_{8} X$ and

$$
\left.X^{\prime}=\left[\mathbf{X}_{1} \ominus_{0}\right),\left(\mathbf{X}_{2}-\theta_{0}\right), \ldots,\left(\mathbf{X}_{n}-\theta_{0}\right)\right]
$$

and

$$
A_{\mathrm{s}}=(\mathrm{n}-\mathrm{s})^{-1} \frac{\phi| | \phi}{\phi \mid \underset{\mathrm{ns}}{\mathrm{n}-\mathrm{s}}}
$$

where the $\phi$ are a matrices of zeroes and $\underset{n-s}{n-s}$ a $(n-s) \times(n-s)$ matrix of ones.

When $\hat{f}_{0}$ is unknown, the test is based on the statistic

$$
\begin{equation*}
T^{(4)}=\Sigma \quad\left(X_{s-} \mid-n-X_{1, s}\right)^{2}[s(n-s) / n], \tag{3.8}
\end{equation*}
$$

and the critical region and power function found by the method of moments as before.

Tables III and IV gives the approximate power of a size $2=.05$ test based on $T^{(3)}$ and $T^{(4)}$ for the same set of parameters used for the one-sided alternatives.

## TABLE I

THE POWERS OF THE ONE-TAILED ( $\theta_{1}>\theta_{0}$ ) MLRT AND THE BAYES BEST WHEN THE INITIAL MEAN ( $\theta_{0}=0$ ) AND VARIANCE ( $\sigma^{2}=1$ ) ARE KNOWN FOR $\mathrm{n}=12$ AND $2=.05$
